PROPERTIES OF BLENDED BARIUM AND STRONTIUM FERRITES

Ye. S. Borovik and N. G. Usikova

Barium and strontium ferrites belong to the hard ferromagnetic materials. But in comparison with the magnetic alloy magnico these ferrites possess lowered residual inductance B_r and less magnetic energy (BH)_{max}, although they do have increased coercive force H_c .

In the literature there are data on increasing magnetic energy in hard ferrites by additives of various oxides [1-3]. In this work the same aim of increasing the magnetic energy of ferrites is pursued and the results of research on the magnetic properties and several physical properties of blended hard ferrites of composition Ba_{1-X} $Sr_{x}0 \cdot 6Fe_{2}0_{3}$ are presented.

Specimen Preparation and Measurement Technique

To prepare specimens of composition $Ba_{i\to X}Sr_X^0$. Fe_2O_3 weight ratios of the powders $BaCO_3$, $SrCO_3$, and Fe_2O_3 were taken corresponding to the needed composition. The powder mixture (in the form of a liquid mass with water) was carefully ground for several hours in a mortar. Then the mixture was dried and roasted for five hours at $1100^{\circ}C$ to form the blended ferrite. The slightly sintered ferrite powder was FTD-TT-62-1539/1+2+4

1

ground in the mortar and from it were pressed specimens at a pressure of about 17 t/cm² without any binding material. The pressed intermediate products were sintered for an hour. Preliminary research showed that the optimum sintering regime lay between 1200-1300°. The specimens were 1 cm long cylinders with a cross-section of about 0.18 cm². The magnetic properties of the specimens were measured by the bridge method in fields up to 7000 oe at room temperature.

Results of Measurement

Figure 1 shows the dependence of the maximum magnetic energy (BH)_{max} on composition for different sintering temperatures (curves 1-4). For a 1200° sintering temperature (curve 1) the magnetic properties of the blended ferrites turn out to be poorer than in pure ferrites. The curve (BH)_{max} as a function of the composition has a minimum for the ferrite Ba_{0.5}Sr_{0.5}0 · 6Fe₂0₃. At this sintering temperature the size of the blended ferrite particles has evidently not yet attained the maximum size of single-domain particles.

For other sintering temperatures the properties of some blended ferrites are found to be better than in pure barium and strontium ferrites. It is evident from Fig. 1 that the curve of the dependence of (BH)_{max} on composition has a maximum for Ba_{0.7}Sr_{0.3}0 · 6Fe₂0₃. The ferrite Ba_{0.25}Sr_{0.75}0 · 6Fe₂0₃ has poorer magnetic properties. The magnitude of the maximum magnetic energy (BH)_{max} in Ba_{0.7}Sr_{0.3}0 · 6Fe₂0₃ specimens at sintering temperature 1230° attains a value of 1.45 · 10° gs · oe, i.e., almost 70% more than in pure barium ferrite and almost 50% more than in pure strontium ferrite. In sintering the specimens at 1300° the nature of the curve changes: the maximum on the curve of magnetic energy is displaced to ferrite Ba_{0.5}Sr_{0.5}0 · 6Fe₂0₃, but

this maximum is already substantially less pronounced and the absolute values of $(BH)_{max}$ for this sintering temperature are less for all the compositions than at 1230° .

The same figure shows the dependence of the residual intensity of magnetization B_r (curve 5) and of the coercive force _IH_c (curve 6) on composition for the best sintering temperature 1230°. At this temperature the maximum B_r is observed in the same ferrite composition in which the minimum occurs on the curve of magnetic energy. A minimum is also observed for Ba_{0.25}Sr_{0.75}0 · 6Fe₂O₃, but the maximum and minimum on this curve are less sharply pronounced than on the magnetic energy curve.

The coercive force curve has one minimum for a composition of approximately $Ba_{0.5}Sr_{0.5}0 \cdot 6Fe_{2}0_{3}$. Changes in the form of the curve of the dependence of $B_{\mathbf{r}}$ on composition connected with the sintering temperature are similar to changes for the curves of $(BH)_{max}$. The shape of the dependence curve of $_{\mathbf{I}}^{\mathbf{H}_{\mathbf{C}}}$ on composition is preserved unchanged for all the investigated sintering temperatures. The absolute values fall at sintering temperatures higher than 1200°.

The same curve nature was observed if the pure ferrites were sintered at optimum temperatures before preparing the blended ferrite and then the specimen of blended ferrite was obtained by re-sintering the pulverized and carefully mixed pure ferrite powders. The effects in this process were, however, much less clearly expressed.

To illustrate the temperature dependence of the investigated properties, Figure 2 shows the dependence curves of magnetic energy (BH) on sintering temperature for differing compositions (curves 1-4) and residual intensity of magnetization B, (curves 5-7).

The curves of (BH) max as a function of the sintering temperature

are in general similar for all compositions, but for a composition near the optimum $(Ba_{0.75}Sr_{0.25}0 \cdot 6Fe_{2}0_{3})$ the most clearly expressed maximum is at a sintering temperature near 1230°. The curves of B_{r} for this ferrite composition have the same nature of temperature dependence with a maximum near 1230°. The temperature dependence of B_{r} for pure ferrites and the ferrite corresponding to composition $Ba_{0.25}Sr_{0.75}0 \cdot 6Fe_{2}0_{3}$ are much less clearly expressed. The growth of B_{r} with the sintering temperature for ferrite $Ba_{0.5}Sr_{0.5}0 \cdot 6Fe_{2}0_{3}$ deserves attention.

The curves of demagnetization for pure barium and strontium ferrites and for blended ferrites with extreme values of the properties (Ba_{0.75}Sr_{0.25}0 · 6Fe₂0₃ and Ba_{0.25}Sr_{0.75}0 · 6Fe₂0₃) are shown in Fig. 3.

Table 1 lists the values of the basic magnetic parameters of pure barium and strontium ferrites and of blended ferrites on magnetization in a field up to 7000 oe for the optimum sintering regime. For comparison the best data in the literature for isotropic ferrites [4] and an example for one of the anisotropic specimens [5] are also listed.

As is evident from Table 1, the properties of the composition near the optimum one are better than the properties of an ordinary isotropic ferrite (the magnitude of (BH)_{max} is 75% greater and approaches the values of the anisotropic ferrite). The authors propose subsequently to investigate anisotropic blended ferrites.

Density and Physical Properties of the Specimens

An investigation of the results of measuring the properties of blended ferrites shows that in these specimens the physical properties also change. Figure 4 displays the curves of change of density of the blended ferrites in relationship to sintering temperature. From a comparison of the curves it is evident that the Ba_{0.75}Sr_{0.25}0 · 6Fe₂0₃ specimen sinters best of all and the Ba_{0.25}Sr_{0.75}0 · 6Fe₂0₃ specimen, poorest of all, the sintering process finishing for the latter at 1230° and its density not changing at a subsequent increase in this temperature.

Table 2 lists the data on measuring microhardness and ultimate strength $\boldsymbol{\sigma}_{\text{ult}}$ during compression.

The ferrite with the optimum magnetic properties also has essentially the best physical properties, compared with pure ferrites. We may achieve an increase in the physical properties of pure ferrites by increasing the sintering temperature and using more active materials,

so that the listed figures for density and strength have only a relative significance. But for practical use it is essential that good physical properties be also found for composition Ba_{0.75}Sr_{0.25}O · · 6Fe₂O₃ which has the best magnetic properties. It is curious to note very poor sinterability and low strength in Ba_{0.25}Sr_{0.75}O · 6Fe₂O₃ ferrite.

Discussion of the Results

In the blended ferrite system $\mathrm{Ba}_{1-\mathrm{X}}\mathrm{Sr}_{\mathrm{X}}0$ · $6\mathrm{Fe}_2\mathrm{O}_3$ a non-monotonic relationship between properties and composition is observed. Ferrite of composition $\mathrm{Ba}_{0.75}\mathrm{Sr}_{0.25}0$ · $6\mathrm{Fe}_2\mathrm{O}_3$ at the optimum sintering temperature has better, and $\mathrm{Ba}_{0.25}\mathrm{Sr}_{0.75}0$ · $6\mathrm{Fe}_2\mathrm{O}_3$ ferrite worse, properties than the pure components. Evidently the former's good properties are essentially caused by the better sinterability of the specimen of this composition. To illustrate this, the relationship of magnetic properties to composition with a correction for porosity was drawn. All the results of measuring magnetization were reduced to the single density value of 4.8 g/cm² by the formula $\mathrm{I}_{\mathrm{corr}} = \mathrm{I}(\frac{4.8}{\rho})^{-2/3}$. This method of introducing corrections is arbitrary to to a certain degree, but since the theoretical density of the blended ferrites is not known to us we must confine ourselves to it.

Figure 5 shows the curves of (BH)_{max} and B_r reduced to a single density at the optimum sintering temperature 1230°. As may be seen, the curve maximum has substantially smoothed out and the minimum has become sharper. Thus, although the shape of the curves is partially cuased by the different sinterabilities of the differently composed specimens, still some other causes evidently lie at the bottom of the observed relationships. Research on the physical properties of such systems will be continued later on, but right now it is already clear

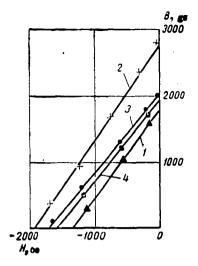

Fig. 3. Demagnetization curves for ferrites of differing composition (sintering temperature 1230°C). 1) Ba_{0.25}Sr_{0.75}O · 6Fe₂O₃; 2) Ba_{0.75}Sr_{0.25}O · 6Fe₂O₃; 3) SrO · 6Fe₂O₃; 4) BaO · 6Fe₂O₃.

TABLE 2

Composition	Microhardness Nee	delt's kg/om²
BaO · 6Fc ₂ O ₃	96,5	2000
SrO · 6Fe ₂ O ₃	106,3	1770
$Ba_{0,25}Sr_{0,75}O \cdot 6Fe_2O_3$	41,2	1770
Ba _{0.5} Sr _{0.5} O · 6Fe ₂ O ₃	885	2800
Ba _{0,75} Sr _{0,25} O · 6Fe ₂ O ₃	600	3500

that blended ferrite Ba_{0.7}Sr_{0.3}0 · 6Fe₂O₃ is a better magnetic material than pure barium and strontium ferrites.

In conclusion we thank Prof. B. Ya. Pines for valuable advice.

A. M. Gor'kiy, State University of Khar'kov
